

Docker

Why and How it works?

Vladyslav Rudenko (@VVRud)

Docker

Docker is a set of platform-as-a-service (PaaS) products that use operating-system-level virtualization to deliver software in packages called **containers**.

Containers are *isolated* from one another and bundle their own software, libraries and configuration files; they can communicate with each other through well-defined channels. All containers are run by a single operating-system kernel and thus more lightweight than virtual machines.

Docker container vs docker image

An instance of an **image** is called a **container**.

You have an **image**, which is a set of layers as you describe.

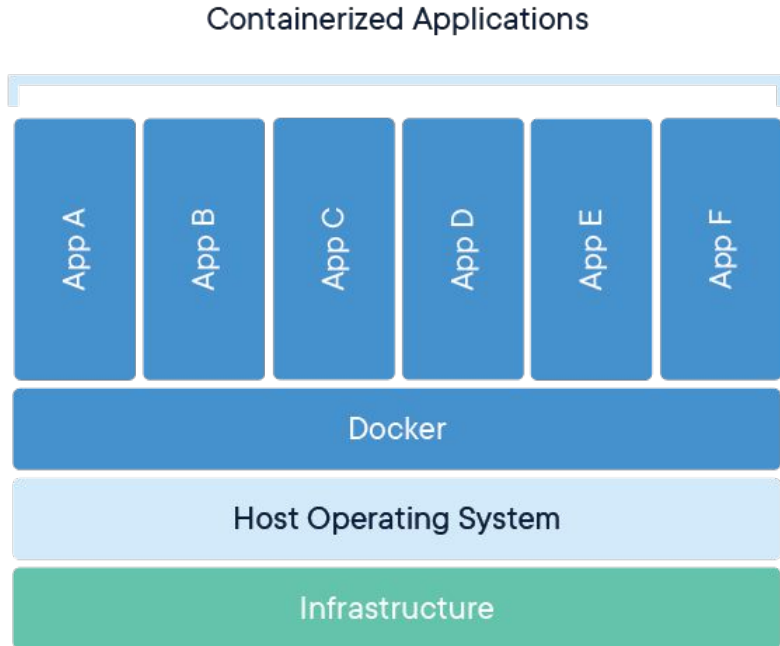

If you start this **image**, you have a running **container** of this image. You can have many running **containers** of the same **image**.

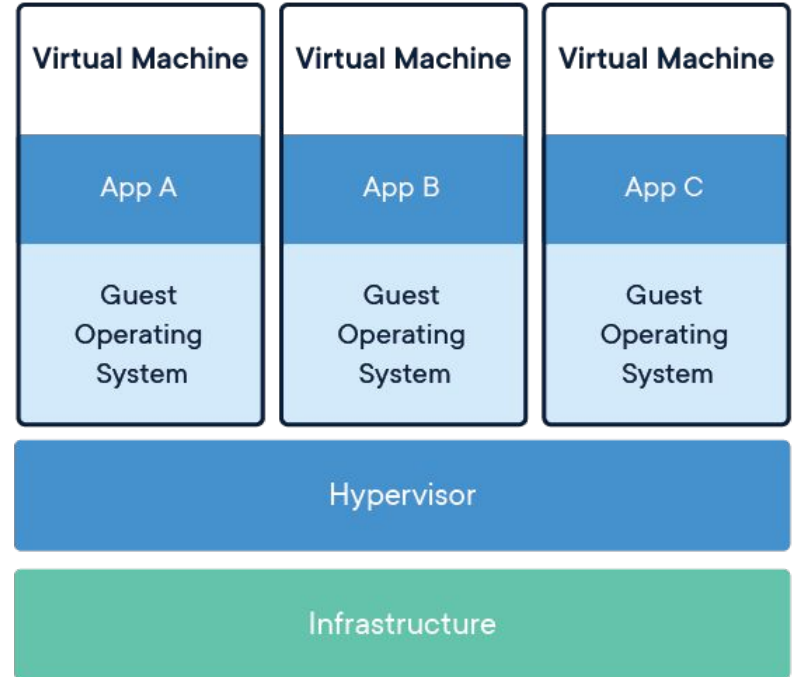

What problems Docker solves?

- missing or incorrect application dependencies such as libraries, interpreters, code/binaries, users;
- conflicts between programs running on the same computer such as library dependencies or ports;
- limiting the amount of resources such as cpu and memory an application can use;
- missing, complicated, or immature scripts to install, start, stop, and uninstall an application.

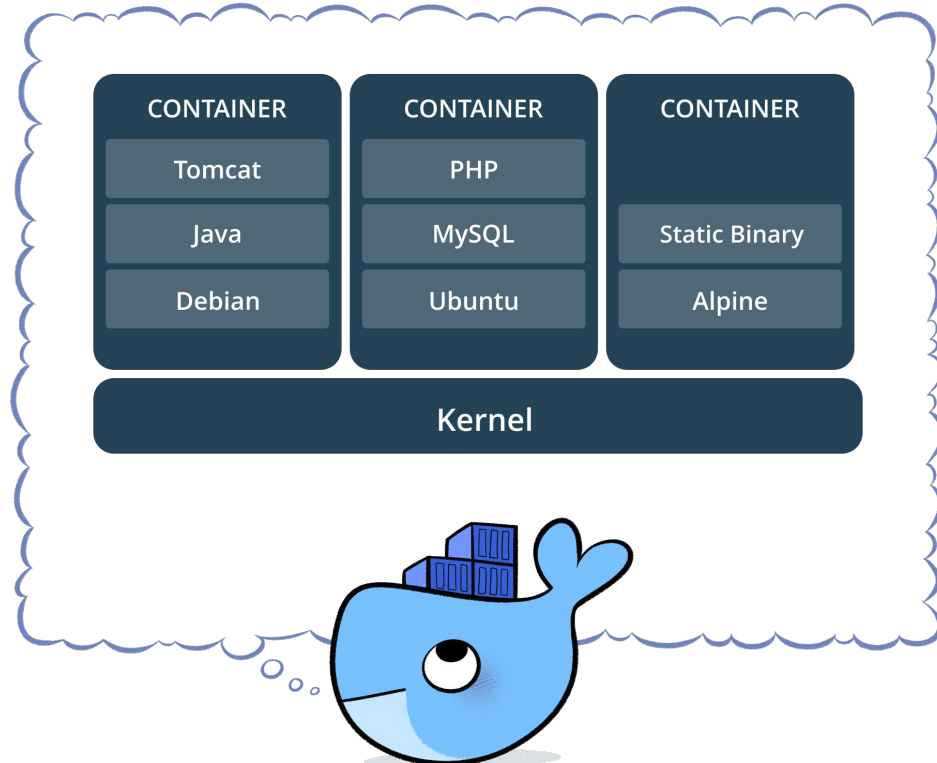

Docker

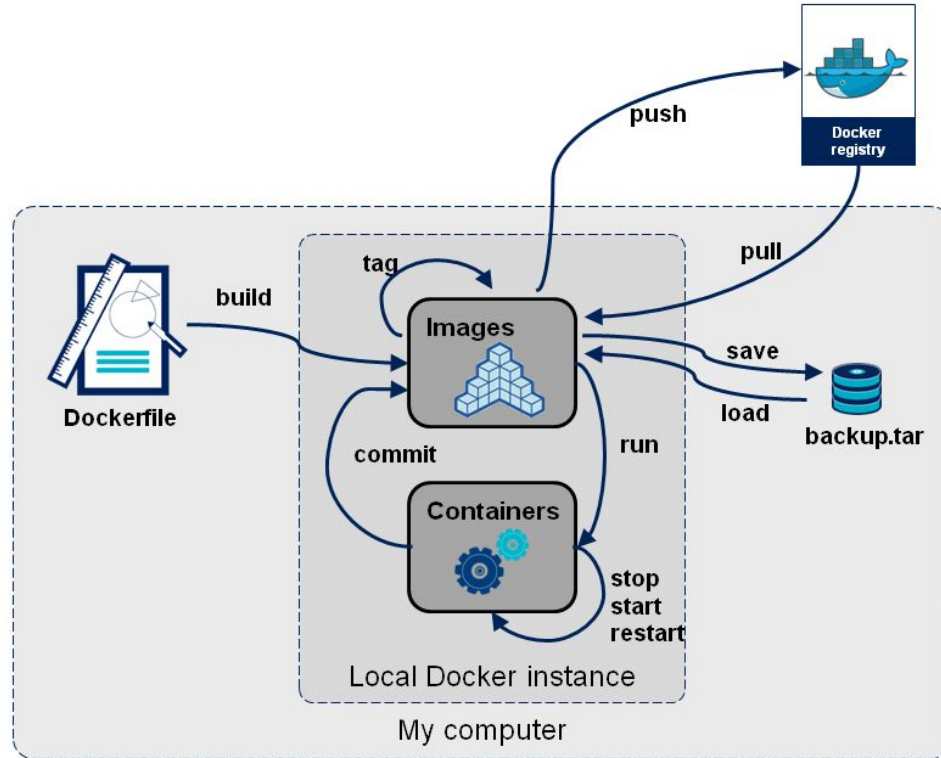

NOT Docker

Docker

Docker life cycle

Dockerfile example

Create an image with **python 3.7.3**

With environment variables **PG_HOST** and **SPLASH_IP** and if they are not set let them be **"localhost"**.

Copy file and **install** libraries it has.

Copy directory with code and **set** it as a **current** directory.

Run command to make file executable.

Run app from command line with parameters **PG_HOST** and **SPLASH_IP**.

```
FROM python:3.7.3

ENV PG_HOST      ${PG_HOST:-'localhost'}
ENV SPLASH_IP    ${SPLASH_IP:-'localhost'}

COPY requirements.txt /requirements.txt
RUN pip install -r requirements.txt

COPY . /crawl_app
COPY ../env.prod ./crawl_app/.env
WORKDIR /crawl_app

RUN chmod +x ./production.sh

CMD ./production.sh ${PG_HOST} ${SPLASH_IP}
```

Docker commands example

```
docker build -t {container_name} {path_to_dockerfile}
```

```
docker run -p {port_outside}:{port_inside} {container_name}
```

```
docker ps
```

```
docker stop {container_id}
```

```
docker rm {container_id}
```

```
docker tag {container_name} {user_name}/{container_name}
```

```
docker push {user_name}/{container_name}
```

Docker Compose

Docker Compose is a ***YAML file*** which contains details about the services, networks, and volumes for *setting up the Docker application*. So, you can use Docker Compose to create separate containers, host them and get them to communicate with each other.

Each container will expose a port for communicating with other containers.

The communication and up-time of these containers will be maintained by Docker Compose.

What problems Docker Compose solves?

- Managing multiple containers/volumes/networks;
- All application stack in one place;
- Easy to run/stop/debug;
- Versioning (in user-readable format).

Docker Compose example

```
1  version: '3.5'
2
3  services:
4    redis:
5      image: redis:latest
6      networks:
7        - internal_net
8      volumes:
9        - './redis_conf/redis.conf:/usr/local/etc/redis/redis.conf:ro'
10       - 'redis_data:/data'
11      entrypoint: redis-server /usr/local/etc/redis/redis.conf
12      restart: always
13
14    postgres:
15      image: postgres:latest
16      environment:
17        POSTGRES_USER: ${POSTGRES_USERNAME}
18        POSTGRES_PASSWORD: ${POSTGRES_PASSWORD}
19        POSTGRES_DB: ${POSTGRES_DATABASE}
20      networks:
21        - internal_net
22      volumes:
23        - 'postgresql_data:/var/lib/postgresql/data'
24        - './postgres_conf/init_postgres.sql:/docker-entrypoint-initdb.d/init_postgres.sql:ro'
25      restart: always
```

```
60  volumes:
61    redis_data: null
62    postgresql_data: null
63
64  networks:
65    internal_net:
66      driver: bridge
67
```

Docker Compose example

```
38  api:
39    build:
40      context: ./api
41      dockerfile: Dockerfile
42    environment:
43      POSTGRES_HOST: postgres
44      POSTGRES_PORT: 5432
45      POSTGRES_USERNAME: ${POSTGRES_USERNAME}
46      POSTGRES_PASSWORD: ${POSTGRES_PASSWORD}
47      POSTGRES_DATABASE: ${POSTGRES_DATABASE}
48
49      REDIS_HOST: redis
50      REDIS_PORT: 6379
51    networks:
52      - internal_net
53    ports:
54      - '8090:80'
55    depends_on:
56      - redis
57      - postgres
58    restart: always
```

```
60    volumes:
61      redis_data: null
62      postgresql_data: null
63
64    networks:
65      internal_net:
66        driver: bridge
67
```

Docker Compose commands example

```
docker-compose build
```

```
docker-compose up -d
```

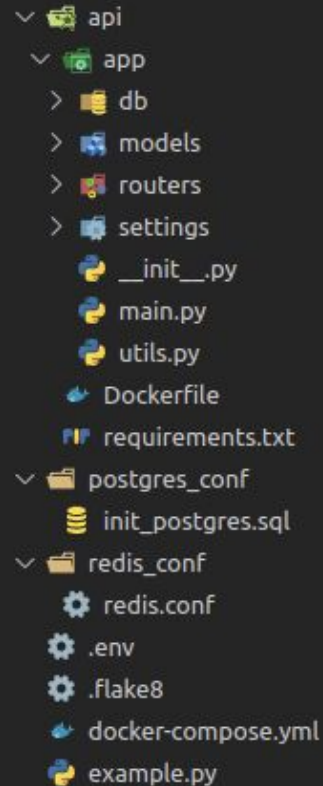

```
docker-compose stop
```

```
docker-compose down -v --remove-orphans
```

```
docker-compose rm
```

```
docker-compose start
```

WORKSHOP TIME!

A screenshot of a file explorer interface with a dark background. The tree view shows a project structure starting with a folder named 'api'. Inside 'api' is a sub-folder 'app'. The 'app' folder contains several sub-folders: 'db', 'models', 'routers', and 'settings'. It also contains three Python files: '__init__.py', 'main.py', and 'utils.py'. Below the 'app' folder are three files: 'Dockerfile', 'requirements.txt', and 'postgres_conf'. The 'postgres_conf' folder contains 'init_postgres.sql'. The 'redis_conf' folder contains 'redis.conf'. At the bottom of the list are three files: '.env', '.flake8', and 'docker-compose.yml'. The last file shown is 'example.py'.

```

  api
  ├── app
  │   ├── db
  │   ├── models
  │   ├── routers
  │   ├── settings
  │   ├── __init__.py
  │   ├── main.py
  │   └── utils.py
  │   ├── Dockerfile
  │   ├── requirements.txt
  │   ├── postgres_conf
  │   │   └── init_postgres.sql
  │   └── redis_conf
  │       └── redis.conf
  │   ├── .env
  │   ├── .flake8
  │   ├── docker-compose.yml
  │   └── example.py

```

Project structure as follows:

- Configurations;
- Apps;
- Variables;

ALL IN ONE PLACE!

Thank you!

God saves the Queen.

Docker saves your time, money and nerves.
